REPLY TO
ATTN OF TE (NAVAIDS Evaluation Section, AV 638-6384)

7 April 1983

SUBJECT TRACALS letter 82/66L-347 to amend TRACALS Evaluation Report, 80/66S-244

TO See Distribution

1. The 1866th Facility Checking Squadron was tasked to perform a special evaluation of the Solid State Instrument Landing System (SSILS) at Tinker AFB, Oklahoma, and produce an amendment to the TRACALS Evaluation Report 80/66S-244. Authority for this action was HQ AFCC/FFNM (now ATTE) letter dated 27 September 1982 referencing CCD/LGM message 232110Z September 1982. The purpose of the evaluation was to update the last TRACALS Evaluation Report after a frequency change of the SSILS and to look at a localizer scalloping problem.
2. The results of the ground equipment checks indicated the localizer was operating within technical order (TO) specifications. The phasing of the course and clearance systems of both transmitters was optimized prior to the flight evaluation. Analysis of the localizer facility siting reconfirmed that line of sight coverage of the runway threshold was limited. The hump in the ground elevation immediately in front of the antenna array reduces the signal strength in the area of the restriction. The flight evaluation conducted by the 1866 FCS reconfirms that the on-course signal begins a gradual bend outside the middle marker and becomes scalloped as the aircraft flies inbound. The severe scalloping on the localizer crosspointer trace results from localizer signal reflections off the buildings along the east side of the runway. Sideband energy transmitted from the antenna array strikes the flat vertical surfaces of these buildings and is reflected at an angle equal to the incident angle. This results in sideband energy being present where a sideband null should exist on centerline; this is approximately in the area from one nautical mile beyond the middle marker to touchdown. This energy, depending on the path length, adds in phase or out of phase to the C+SB component to produce an alternating condition of predominating 90 or 150 hertz, resulting in the observed scalloping. The terrain conditions amplify the reflection problem. The terrain immediately in front of the localizer array rises, which causes screening to become a factor. The Runway 17 threshold is approximately 30 feet below the localizer line of sight coverage. The terrain is relatively flat in the direction of the buildings that cause the reflections; therefore, the energy from the reflective surfaces that combines with the direct energy on course is higher in magnitude than would be the case if the intervening terrain allowed line of sight coverage of the Runway 17 threshold. Excursions on the crosspointer trace exceed AFM 55-8 tolerances as can be seen from Attachment 5. The reflection off of the large hangar doors on building 3102 are most likely the cause of the localizer alignment measurements exceeding these tolerances. Analysis of reflection cancellation methods such as cancellation wires and corrective "cosmetic" panels indicate the cost of such methods would be greater than their benefits, especially since the Runway 17 SSILS is a Catagory I system. The restriction "localizer unusable from middle marker inbound" should remain. As mentioned in the original report, an approximate 30 percent reduction in the severity of the scalloping can be accomplished by widening the course width from 3.3 to 5.0 degrees. This non-tailored course width would be in accordance with AFM 55-8, Change 32, para 217.3206.

83 05 09 165

3. The glide slope was operating within TO specifications, as revealed by the facility ground equipment checks. The flight evaluation indicated the glide slope met AFM 55-8 flight inspection requirements as a Category I facility. A step, at times, was noted above path which made determination of a repeatable path width difficult. No significant glide slope performance deficiencies were detected. A fly down indication was noted from Point B to threshold. Terrain in the first Fresnel zone is the most likely cause. The original report provides further discussion of this.

4. Attachments 4 through 8 of this letter reflect the current changes in equipment operating conditions due to the frequency change. The SSILS frequency change did not change any of the narrative of the previous TRACALS Evaluation Report. Please ensure the contents of this amendment are disseminated to all users of this report within your unit. This letter should be attached to the previous report for future reference.

ATTN OF FFNM

SUBJECT Special TRACALS Evaluation, Tinker AFB OK, AN/GRN-29 (CCD/LGM 232110 Sep 82)

TO 1866 FCS/TE

Request you provide a team to support the subject evaluation. Team should be available to gather and assemble data during the flight check which is tentatively scheduled for 26 or 27 Sep 82. Data should be gathered which will allow you to amend Report No. 80/665-244.

SUBJ: SPECIAL TRACALS EVALUATION TINKER AFB AN/GRN-29
REQUEST A SPECIAL TRACALS EVALUATION BE CONDUCTED DURING THE WEEK OF
27 SEP-3 OCT 82 ON THE TINKER AFB AN/GRN-29 TO UPDATE THE CEC BC
EVALUATION REPORT AND RESTORE THE FACILITY TO SERVICE. PRESENTLY
THE ILS IS OUT OF SERVICE DUE TO MAINTENANCE CHANGING THE FREQUENCY
TO PROVIDE TINKER AFB WITH DISCRETE FREQUENCIES. THIS LOCALIZER HAS
A RESTRICTION FROM THE MIDDLE MARKER IN DUE TO SEVERE SCALLOPING.
WE FEEL IT IMPRATICABLE TO GET A FRESH LOOK AT THE LOCALIZER TO DETER-
MINE THE OPERATIONAL CAPABILITIES AND LIMITATIONS OF THE SYSTEM AT
THE NEW FREQUENCY AND PUBLISH AN UPDATED REPORT FOR FUTURE REFERENCE.
THIS CONFIRMS TELECON WITH MR. CONLEY AFCC/FFN, MR. SMITH 1985CS AND
MR. BAENES THIS OFFICE.

20. ABSTRACT (Continue on reverse side if necessary and identify by block number) This report presents the results of the 8-20 December 1980 Special TRACALS Evaluation of the Tinker AFB AN/GRN-29 SSILS. The evaluation was conducted to determine the capabilities and limitations of the system in its installed environment and determine the cause of the present localizer restriction. Results presented in this report can be used as a guide for anticipated performance until there is a significant change in ground equipment, siting environment, screening, or operational use.

1. SUMMARY

1-1. Background. Wilcox Electric, Inc., began the installation of the AN/GRN-29 SSILS at Tinker AFB in December 1977. An official Federal Aviation Agency (FAA) flight inspection was requested to commission the facility in November 1978. The glide slope was commissioned as an unrestricted Category I facility. However, the localizer was restricted and declared "unusable below 300 feet within 1.0 nautical mile (NM) due to localizer reversals." The DD Form 250, Material Inspection and Receiving Report, was signed by Electronic Systems Division (ESD) since Wilcox Electric, Inc., had met their contractual obligation. The commander of Tinker AFB was hesitant to accept the AN/GRN-29 Solid State Instrument Landing System (SSILS) since its operation was not consistent with the base operational requirements. ESD requested the Traffic Control and Landing Systems (TRACALS) Engineering Branch of Southern Communications Area (SCA) to do an engineering analysis of the localizer at Tinker AFB. This analysis was completed in May 1979 and concluded the cause of the restriction was reflections from buildings 3001, 3102, and 3105. The effects of these reflections were minimized by positioning the antenna nulls using the stacking method and rephasing the system in the far field. The facility remained unrestricted from May 1979 to July 1980. The distribution unit was replaced in June 1980 and the FAA restoral flight inspection restricted the facility "unusable from the middle marker inbound." SCA/FFN then requested the 1866 FCS perform a special TRACALS Evaluation of the Runway 17 localizer.

1-2. Evaluation Profile. A Special TRACALS Evaluation was conducted during the period 8-20 December 1980 on the Tinker AFB AN/GRN-29 SSILS. The purpose of the evaluation was to determine the operational capabilities and limitations of the system in its installed environment and determine the exact nature and cause of the restriction to the Runway 17 localizer. The special evaluation was requested by SCA to determine why the facility was restricted inbound from the middle marker. To define the entire system capabilities, the glide slope facility was also evaluated. The evaluation consisted of three phases: ground equipment checks, facility siting, and flight evaluation. The ground equipment checks determine if the facility is operating within technical order (TO) specifications and what actions are necessary to optimize the system. The facility siting was evaluated to identify any possible interference to the radiated signal. The flight evaluation determines the exact nature of the radiated pattern and defines the flyability of the system.

1-3. Localizer:

a. Siting. The AN/GRN-30 localizer is sited at the south end of Runway 17/35. The antenna array is situated on a wooden trestle. The elevation of the antennas is just above the crest of the runway overrun, which lies 1000 feet north of the antennas (see page A5-1). Large buildings are located east of the localizer and are oriented parallel to the runway. Although these buildings are not specifically in violation of AN/GRN-29 siting criteria, it is generally accepted that they should not be within 10° of the runway centerline. These buildings are less than 1000 feet from the runway at an angle of about 4° to the localizer centerline. The terrain in the direction of the buildings does not slope up as much as in the direction of the runway. A drawing depicting the building locations is on page A6-1.

b. Evaluation Results. The results of the ground equipment checks indicated, for the most part, the localizer was operating within TO specifications. The phasing of the course and clearance systems of both transmitters was optimized prior to

the flight evaluation. Transmitter two requires additional cable cutting to center the course and clearance sideband phasers. Analysis of the facility siting indicates all antennas do not have line of sight to the threshold. A rise in the ground elevation immediately in front of the antenna array causes a reduced signal strength in the area of the restriction. The flight evaluation revealed that the on-course signal begins a gradual bend outside the middle marker and becomes scalloped as the aircraft flies inbound.

c. Conclusions. Severe scalloping on the localizer crosspointer trace results from reflections off the buildings along the east side of the runway. Siting conditions amplify the reflection problem. The terrain immediately in front of the localizer array rises, causing a reduced signal strength on course. However, the terrain conditions in the direction of the reflections are relatively flat. This means the reflected energy is higher in magnitude than would be the case if the terrain slope were consistent. Excursions on the crosspointer trace do not exceed AFM 55-8 tolerances, but as occurred in the past, slight variations in equipment performance, variations in flight inspection measurement, and position of the large hangar doors on building 3102 will likely result in exceeding these tolerances. The restriction "localizer unusable from middle marker inbound" should remain. An approximate 30% reduction in the severity of the scalloping can be accomplished by widening the course width from 3.3° to 5.0° . This non-tailored course width would be in accordance with AFM 55-8, Change 32, para 217.3206. Other actions involving antenna relocation would require some trial and error, with the cost benefits being questionable.

1-4. Glide Slope:

a. Siting. The glide slope is installed on the east side of the runway 935 feet from the threshold of Runway 17 and 412 feet from the runway centerline. The terrain in the first Fresnel zone is profiled on page A7-1. Some upslope occurs north of Interstate 40, which crosses the approach. A contour study encompassing the first Fresnel zone terrain is presented on page A7-2. Horizon screening for the glide slope is shown on pages A8-4 thru A8-6 and indicates no significant areas of concern.

b. Evaluation Results. With the exception of the width monitor alarm points, the ground equipment checks revealed the facility was operating within TO specifications. A recent change to the TO tightened the width monitor alarm points but the work cards were not changed. Since a disparity existed between the work cards and the TO, the alarm points were adjusted to TO specifications. The siting of the facility was satisfactory for Terminal Instrument Approach Procedures (TERPS) requirements. The flight evaluation indicated the glide slope met AFM 55-8 flight inspection requirements as a Category I facility. A step, at times, was noted above path which made determination of a repeatable path width difficult.

c. Conclusions. The results of the glide slope evaluation indicate the facility can provide satisfactory Category I operation. To obtain Category II operation would require optimizing the antenna offset and modifying the near field terrain to improve the structure in Zone 3.

1-5. Power Systems. The primary and backup power systems of both the localizer and glide slope were checked during the evaluation period. The backup power appeared adequate and reliable. The primary power at the glide slope appeared slightly high and the local maintenance personnel were advised to notify the base CE.

2. RECOMMENDATIONS

2-1. Localizer:

(1) Prior to the next periodic flight inspection, the new cabling for transmitter two should be cut to center the course and clearance sideband phasers.

(2) The 1985th Communications Squadron should explore the operational consequences of increasing the localizer course width to 5.0° .

2-2. Glide Slope. No recommendations.

3. GENERAL INFORMATION

3-1. Primary Using Agencies/Aircraft Supported. The primary using agencies are the 552nd Airborne Warning and Control Systems Wing with E-3A aircraft, and the 507th Tactical Fighter Group with F-4 aircraft. Additionally, there are a large number of transient aircraft of all types, civilian and military transport aircraft, and various aircraft undergoing overhaul by the Oklahoma City Air Logistics Center. An aeronautical chart showing the location of Tinker AFB is on page A1-1.

3-2. Air Traffic Control Facilities. The Air Traffic Control systems supporting the Tinker AFB operation are an AN/FPN-47 radar owned and operated by the FAA, an AN/GRN-19A TACAN, an AN/GRN-27 SSILS serving Runway 35, an AN/GRN-29 SSILS serving Runway 17, and a VFR control tower. The AN/GRN-29 SSILS provides Category I instrument approaches to Runway 17. These procedures are outlined on pages A2-1 and A2-2.

3-3. Terminal Instrument Approach Procedures. Information concerning the TERPS are contained in the facility data sheets on pages A3-1 thru A3-4. The method used to calculate the TCH, GPI, and RPI are shown on page A4-1. These calculations are based on a rapid decrease in elevation toward the runway.

4. ANALYSIS OF EVALUATION RESULTS

4-1. Localizer:

a. Ground Equipment Checks. The results of the localizer initial performance and subsystem checks are on pages A9-1 thru A10-4. A record of the ground checks accomplished during the evaluation is on pages A11-1 and A11-2. Graphs of the ground checks are on pages A12-1 thru A12-8.

(1) Course Phasing. The course phasing of both transmitters was less than optimum. The phasing was adjusted at the far field 3° phasing points for as close to 0° DDM as possible, balanced between the 90° Hz and 150° Hz sides. Following this adjustment, the sideband phasers indicated 10° and 20° delay, respectively, for transmitters one and two. To center the phaser on transmitter one, two inches was cut from the C+SB cable (6W29) at the distribution unit. The phaser for transmitter two now indicated 10° delay while transmitter one was approximately 0° . To center the phaser on transmitter two, a longer transmitter SBO cable is required. This was not accomplished during the evaluation because the cable and connectors were unavailable. The local maintenance personnel should fabricate and install a longer SBO cable prior to the next periodic flight inspection.

(2) Clearance Phasing. The clearance phasing of both transmitters was significantly less than optimum (see pages A12-3 and A12-4). To center the phaser of transmitter one, eight inches was cut from the SBO cable (6W32) at the distribution unit. The sideband phaser of transmitter two was still about 10° advanced and will require a longer C+SB transmitter cable. The fabrication and installation of this cable should be done in conjunction with the course cable. Final results of the clearance phasing can be seen on pages A12-5 and A12-6.

(3) Antenna Nulls. Some difficulty was encountered in determining the placement of the antenna RF nulls. Several methods were employed during the evaluation.

(a) TO Procedures. The single tone DDM method was attempted using the GRM-112 Portable ILS Receiver (PIR) with little success. A dip in the DDM indication could be seen for pairs six and seven, but no change for any other pair.

(b) RF Null. The traditional method of determining the null placement is to find the RF minimum. This was attempted using the GRM-112 PIR, again with little success. The meter sensitivity of the GRM-112 makes it extremely difficult to see an RF dip. The RF level meter indication from 10 to 50 represents signal strengths from -80 dBm to +10 dBm with a nonlinear response. The RF minimum was only one meter movement division or less. Where no dip was observed, an attempt was made to measure the null using the bracket method. The PIR was moved until the meter movement increased to some reference level. The PIR was then moved to the other side of the runway centerline until the same reference level was found. One half the distance between these two locations was considered the null position. Displacement was calculated by measuring from this point to the runway centerline. The results of the RF null checks are on page A10-1.

(c) Null Stacking. SCA Engineering used a method called null stacking in March 1979. They recommended all future null placements required at Tinker AFB be accomplished using this method. Pair seven is radiated separately, both C+SB and SBO, and the null adjusted to 0 DDM using the far field monitor indication. Pair six is then added and its cabling adjusted for a combined reading of 0 DDM. This process is repeated for each antenna pair until all seven pairs are radiating. The local maintenance personnel used this method following the replacement of the distribution unit in June 1980. During the TRACALS Evaluation, this procedure was followed but no adjustments were made. The DDM on centerline and the distance to the DDM null were also recorded at the 1000 feet ground check point (see page A10-4). This test indicated pairs seven, four, and probably three could all be further adjusted. Positioning the null to centerline would not have significantly improved the overall course signal and no action was taken by the TRACALS team.

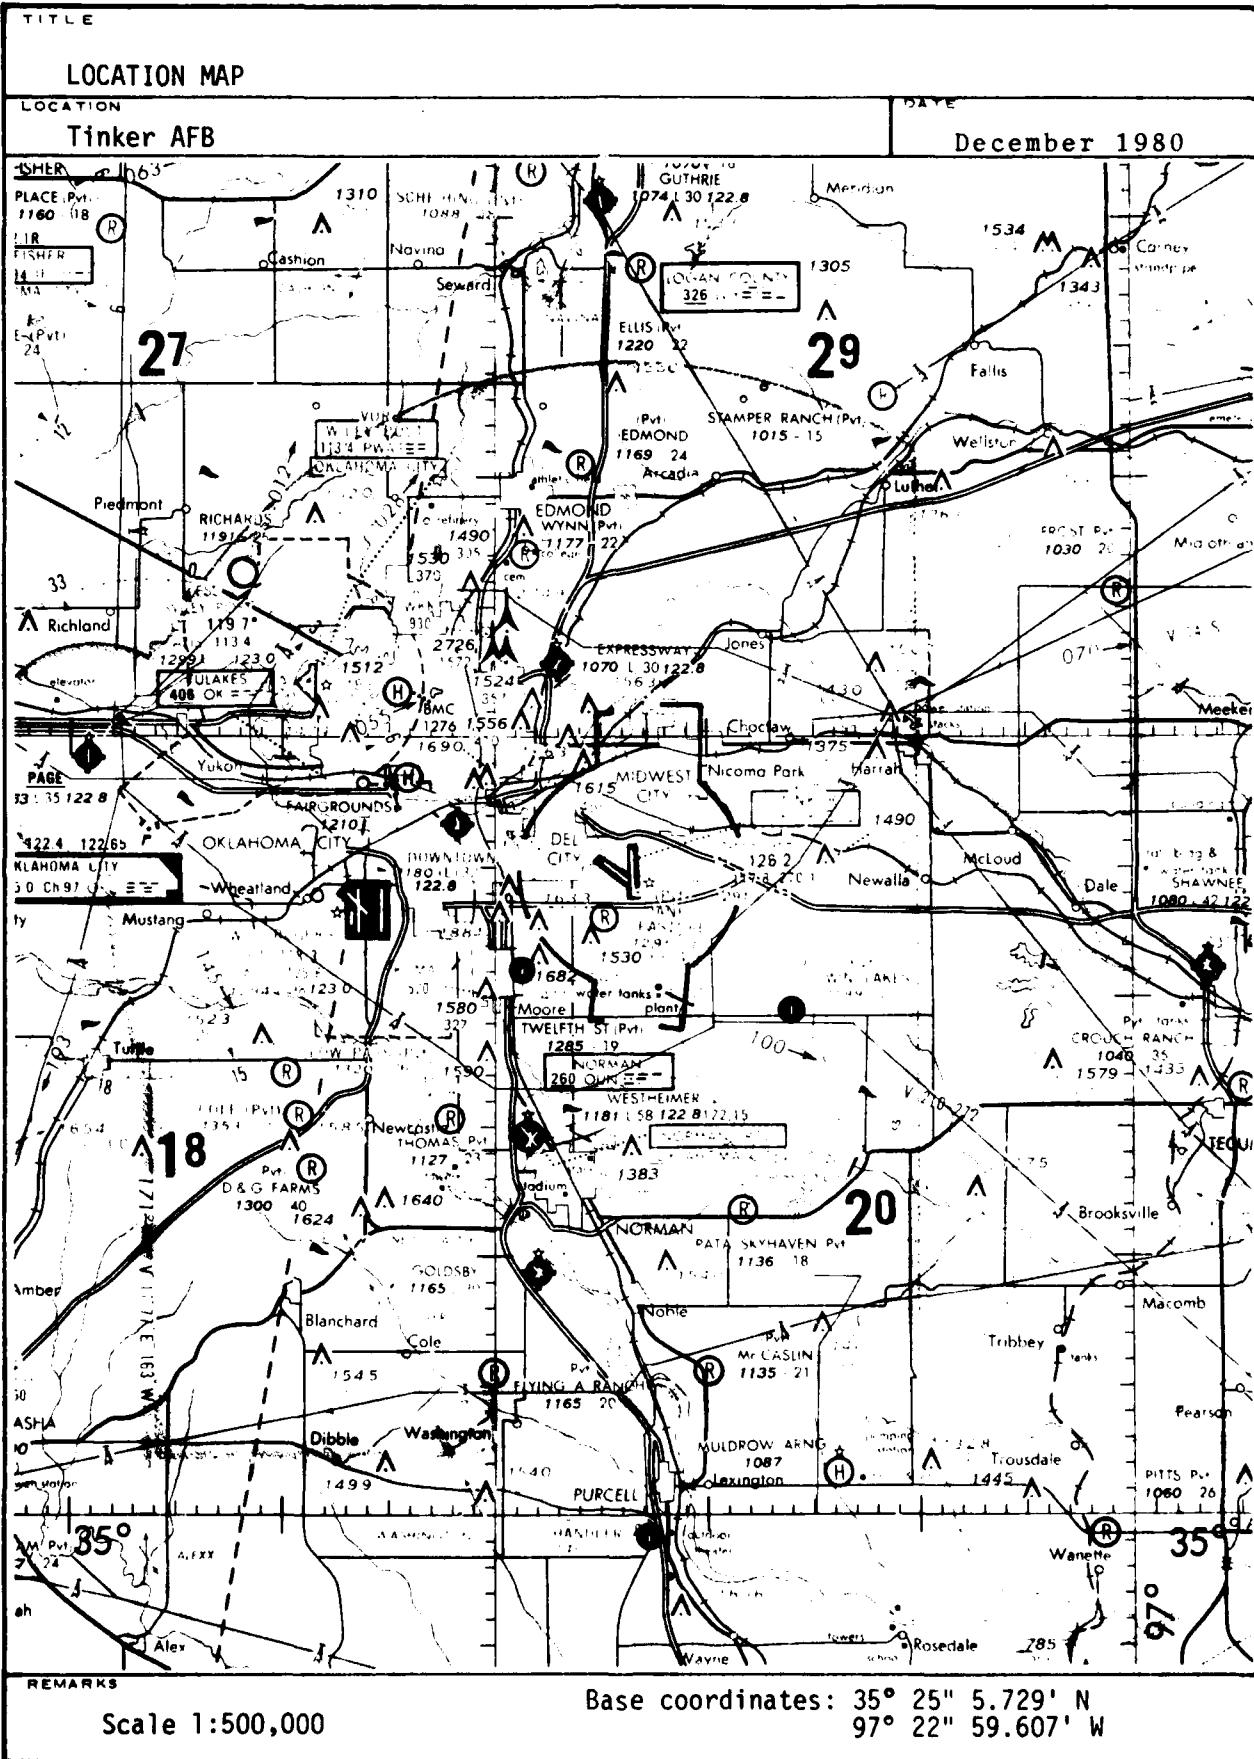

b. Flight Evaluation. Severe scalloping on the localizer crosspointer trace (see page A18-9) results from reflections from buildings along the east side of the runway. Sideband energy transmitted from the antenna array strikes the flat vertical surfaces of these buildings and is reflected at an angle equal to the incident angle. This energy results in sideband energy being present where a sideband null should exist on centerline, approximately in the area from 1 NM beyond the middle marker to touchdown. This energy, depending on the path length, adds in phase or out of phase to the C+SB component to produce an alternating condition of predominating 90 Hz or 150 Hz, resulting in scalloping. The terrain conditions amplify the reflection problem. The

terrain immediately in front of the localizer array rises, which causes a reduced signal strength on course. In fact, the Runway 17 threshold is approximately 30 feet below line of sight from the localizer. However, the terrain is relatively flat in the direction of the buildings that cause the reflections. This means that the energy from the reflective surfaces that combines with the direct energy on course is higher in magnitude than would be the case if no upslope existed.

4-2. Glide Slope:

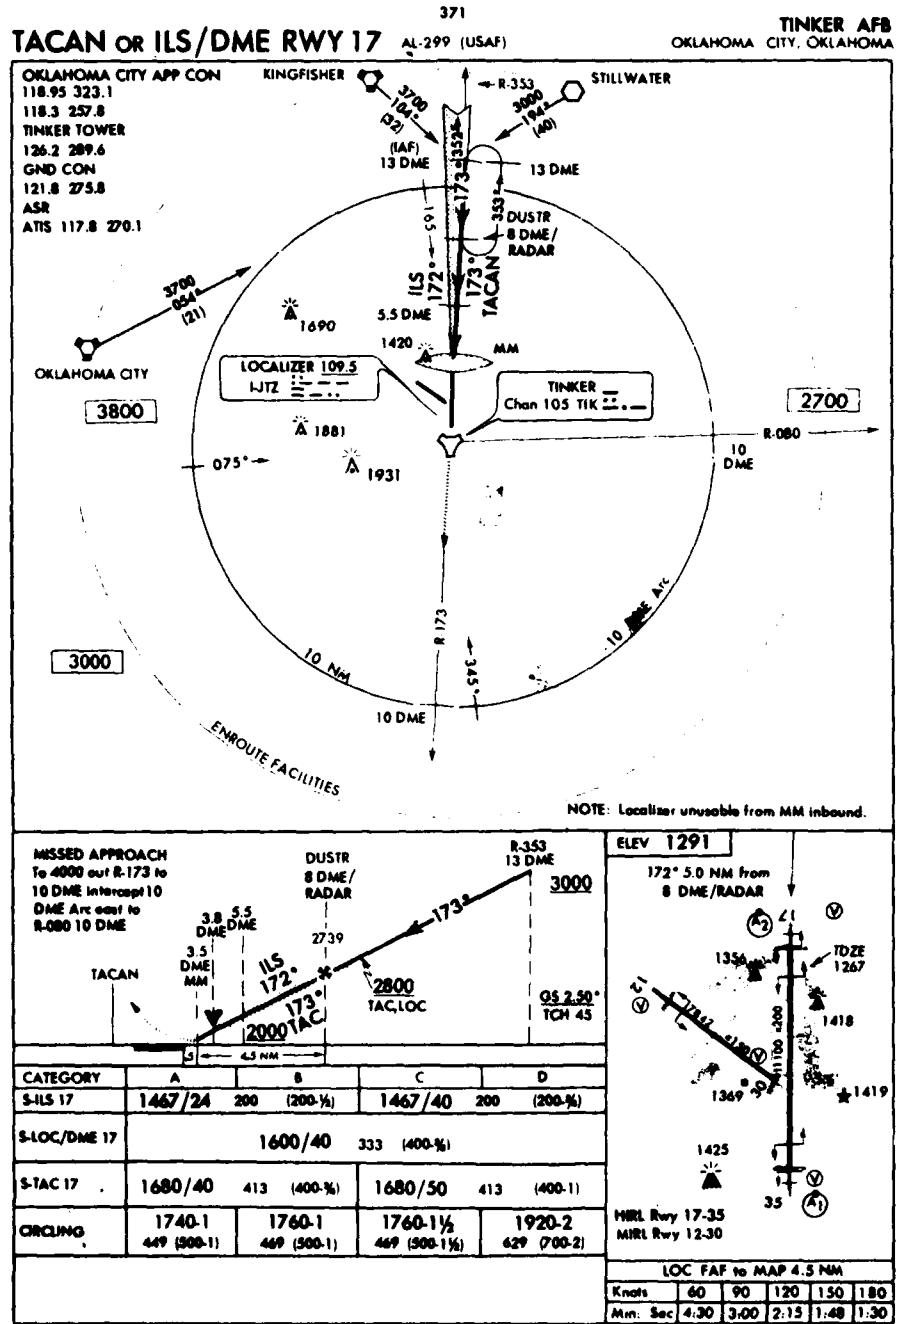

a. Ground Equipment Checks. With the exception of the width monitor alarm points, the ground equipment checks indicated the facility was operating within TO specifications. Change 3 to TO 31R4-2GRN31-2 changed the width alarm points from 0.145 DDM to 0.155 DDM and 0.205 DDM to 0.195 DDM. This change was required because some facilities were having difficulty meeting the advance and retard to alarm tolerance during flight checks. The workcards, TO 31R4-2GRN-6WC-1, have not been changed to reflect the new alarm points. Since a conflict exists between the TO and the workcards, the TO tolerances were applied during the evaluation. The local maintenance personnel should submit an AFTO Form 22 to correct this discrepancy.

b. Flight Evaluation. No significant glide slope performance deficiencies were detected. A fly down indication was noted from Point B to threshold. Terrain in the first Fresnel zone (see page A20-1) is the probable cause. As the aircraft approaches the threshold and the Fresnel zone swings in that direction and shortens, the terrain that develops the glide angle slopes downward more rapidly which results in driving the glide angle down. The deviation in phasing is probably also caused by the same terrain condition. That could be corrected by adjusting the antenna offset. It was not considered necessary since the deviation is inside Point B. The facility was evaluated with the theodolite positioned in line with the RPI and an elevation angle of 2.5° . The straight line structure (except for the fly-down indication in close) indicates the facility is properly sited and aligned to meet the 45.4 feet TCH.

* - Change 3 to TO 31R4-2GRN31-2 changed the width monitor alarm points from 0.145 to 0.155 and from 0.205 to 0.195. The workcards, 31R4-2GRN31-6WC-1, have not been changed. TO tolerances were applied during the TRACALS Evaluation and the monitors tightened up to the TO specification. Local maintenance will submit an AFTO Form 22.

** - The "ADJUSTED" readings were recorded following the flight evaluation.

*** - Far field modulation balance and phasing were accomplished at the Localizer far field monitor.

12. REMARKS													
<p>1. This was a special inspection/TRACALS Evaluation of number 1 transmitter, on an AN/GRN-29 ILS to RWY 17. Periodic requirements were fulfilled on both transmitters. TRACALS Evaluation was to investigate possible corrective actions for localizer structure problems from 1.5NM to threshold.</p> <p>2. Localizer alignment and structure and glide slope actual angle and structure</p>
